A Market Design Perspective on the HFT Debate: The Case for Frequent Batch Auctions

Eric Budish, University of Chicago

FCA/LSE Conference on Financial Regulation

Feb 2016

A Simple Idea: Discrete-Time Trading

- My research identifies a simple structural flaw in the design of modern financial exchanges
- HFT has both positive and negative aspects – many of the negative aspects are *symptoms* of this structural flaw
- The flaw is that trading occurs in "continuous time"
  - Orders processed one-at-a-time in order of receipt (serial)
  - In a race, someone is always first (even if by a nanosecond)
- Solution: trade in "discrete time"
  - Time in units of e.g. 100ms or 10ms. (very fast, but a long time for a computer)
  - Orders processsed all-at-once at end of time interval, using an auction (batch processing)
- Benefits of discrete-time trading, aka "frequent batch auctions"
  - Enhances liquidity: competition on speed -> price
  - Eliminates latency arbitrage. Stops the latency arms race
  - Simplifies the market computationally – for exchanges, regulators, algos, investors

(Source: Budish, Cramton and Shim, 2015, *Quarterly Journal of Economics*)

The Case for Frequent Batch Auctions

A simple idea: discrete-time trading.

1. Empirical facts: continuous markets don't "work" in continuous time
   - Market correlations completely break down.
   - Frequent mechanical arbitrage opportunities.
   - Mechanical arbs –> arms race. Arms race does not compete away the arbs, looks like a "constant".
2. Root flaw: continuous-time trading
   - Mechanical arbs are "built in" to the market design. Sniping.
   - Harms liquidity.
   - Induces a never-ending, socially wasteful, arms race for speed.
3. Solution: frequent batch auctions
   - Competition on speed –> competition on price.
   - Enhances liquidity and stops the arms race.
   - Simplifies the market computationally

The Case for Frequent Batch Auctions

Latency Arb and Arms Race are "Constants" of the Market Design

To summarize:

- Competition does increase the speed requirements for capturing arbs ("raises the bar")
- Competition does not reduce the size or frequency of arb opportunities
- Suggests we should think of latency arbitrage and the resulting arms race as a "constant" of the current market design

The Case for Frequent Batch Auctions

A simple idea: discrete-time trading.

1. Empirical facts: continuous markets don't "work" in continuous time
   - Market correlations completely break down.
   - Frequent mechanical arbitrage opportunities.
   - Mechanical arbs –> arms race. Arms race does not compete away the arbs, looks like a "constant".
2. **Root flaw: continuous-time trading**
   - **Mechanical arbs are "built in" to the market design. Sniping.**
   - **Harms liquidity.**
   - **Induces a never-ending, socially wasteful, arms race for speed.**
3. Solution: frequent batch auctions
   - Competition on speed –> competition on price.
   - Enhances liquidity and stops the arms race.
   - Simplifies the market computationally

Model: Key Idea

Key idea: think about mechanical arbitrages from a liquidity provider's perspective

- Suppose there is a publicly observable news event that causes his quotes to become "stale"
  - E.g., a change in the price of a highly correlated security, central bank announcement, company announcement
- Liquidity provider will try to adjust his stale quotes
- At same time, many others will try to "snipe" his stale quotes
- In a continuous limit order book, messages are processed one-at-a-time in *serial* ...
- so the 1 usually loses the race against the Many ...
- Even if he, too, is at the cutting edge of speed

Model: 3 Key Takeaways

1. Mechanical arbs like ES-SPY are "built in" to the market design
   - *Symmetrically observed public information creates arbitrage rents.*
   - This isn't supposed to happen in an efficient market.
   - OK to make money from asymmetric information, but symmetric information is supposed to get into prices for free. Market failure.
2. Profits from mechanical arbs come at the expense of liquidity provision
   - In a competitive market, sniping costs get passed on to investors.
   - Thinner markets, wider bid-ask spreads.
3. Sniping creates a never-ending race for speed
   - Snipers: win race to pick off stale quotes.
   - Liquidity providers: get out of the way of the snipers!
   - HFT arms race is a *symptom* of flawed market design

Clarifying Remark: Role of HFTs

Role of HFTs

- In our model HFTs endogenously perform two functions
  - Useful: liquidity provision / price discovery
  - Rent-seeking: sniping stale quotes
- The rent-seeking may seem like zero-sum activity among HFTs
  - But this misses the economics: sniping is like a tax on liquidity provision, which in turn harms non-HFTs
- Clarification
  - Our results do *not* imply that on net HFT has been bad for liquidity or social welfare
  - Our results *do* say that sniping is bad for liquidity and the speed race is socially wasteful
  - Frequent batch auctions preserve (in a sense, enhance) the useful function that HFTs perform while eliminating sniping and the speed race

Clarifying Remark: Empirical Evidence on HFT and Liquidity

Consistent with "IT Good, Speed Race Bad"

The Case for Frequent Batch Auctions

A simple idea: discrete-time trading.

1. Empirical facts: continuous markets don't "work" in continuous time
   - Market correlations completely break down.
   - Frequent mechanical arbitrage opportunities.
   - Mechanical arbs –> arms race. Arms race does not compete away the arbs, looks like a "constant".
2. Root flaw: continuous-time trading
   - Mechanical arbs are "built in" to the market design. Sniping.
   - Harms liquidity.
   - Induces a never-ending, socially wasteful, arms race for speed.
3. **Solution: frequent batch auctions**
   - **Competition on speed –> competition on price.**
   - **Enhances liquidity and stops the arms race.**
   - **Simplifies the market computationally**

Frequent Batch Auctions: Overview

- High level: analogous to the current market design but for two key differences
  - Time is treated as discrete, not continuous
  - Orders are processed in batch, not serial

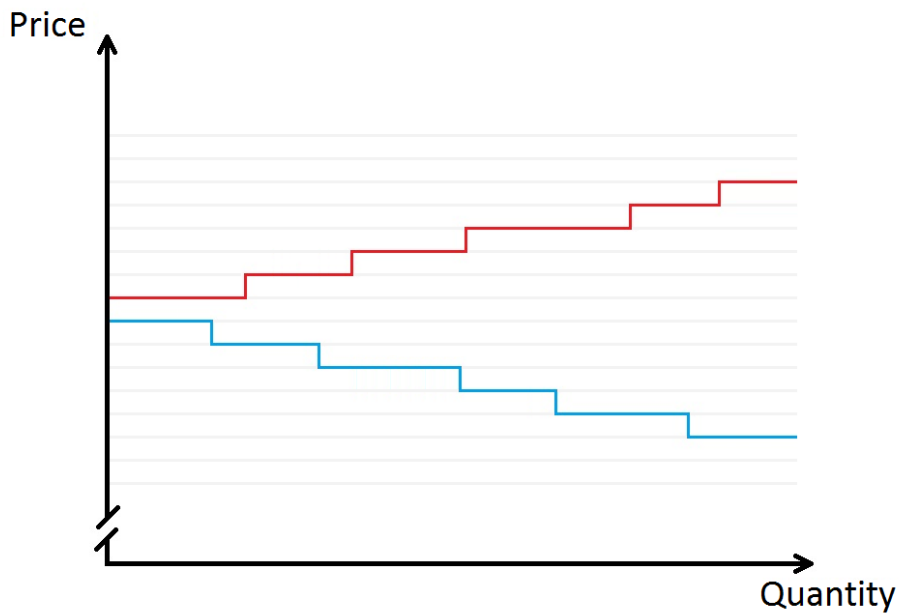
Frequent Batch Auctions: Definition

- During the batch interval (eg 100ms) traders submits bids and asks
  - Can be freely modified, withdrawn, etc.
  - If an order is not executed in the batch at time t, it automatically carries over for $t+1, t+2, \ldots,$
  - Just like standard limit orders
- At the end of each interval, the exchange "batches" all of the outstanding orders, and computes market-level supply and demand curves
- If supply and demand intersect, then all transactions occur at the same market-clearing price ("uniform price")
- Priority: still price-time, but treat time as discrete. Orders submitted in the same batch interval have the same priority. Pro-rata to break ties.
- Information policy: info is disseminated in discrete time. After each auction, all orders active for the auction displayed publicly
  - Activity during the interval is not displayed publicly (gaming)
  - Discrete time analogue of current practice in a CLOB market

Frequent Batch Auctions: 3 Cases

Case 1: Nothing happens during the batch interval

- Very common case: most instruments, most 100ms periods (or shorter), there is zero trade
- All outstanding orders carry forward to next interval
- Analogous to displayed liquidity in a LOB market

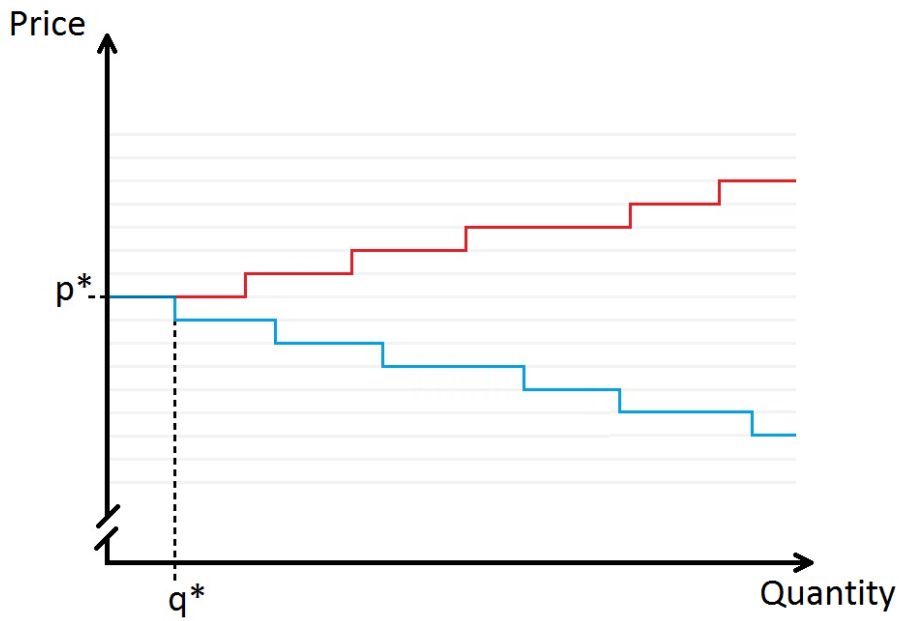


Case 1: No Trade

Frequent Batch Auctions: 3 Cases

Case 2: Small amount of trade

- Example: an investor arrives wanting to buy a small amount at market
- Demand will cross supply at the bottom of the supply curve
- Analogous to trading at the ask in a LOB market



Case 2: Investor Buys q*

Frequent Batch Auctions: 3 Cases

Case 3: Burst of activity in the interval

- Example: there is public news and many algos respond
- In this case, FBA and CLOB are importantly different
- CLOB: process burst of activity based on order of receipt: competition on speed
- FBA: process burst of activity using an auction: competition on price
- Helps liquidity in 2 ways
  1. Liquidity providers have until end of interval to adjust their quotes to reflect new info
     - Being tiny bit slower than competition almost never matters
  2. Liquidity providers are protected by the auction: get a market consensus price based on new info
     - No more sniping. Public information induces price competition, not speed competition

Computational Benefits of Discrete Time

- Overall
  - Continuous-time markets implicitly assume that computers and communications technology are infinitely fast.
  - Discrete time respects the limits of computers and communications. Computers are fast but not infinitely so.
- Exchanges
  - Eliminates backlog problem (65ms on 10/15/2014, even for state-of-art matching engine)
  - Simplifies message processing (CME trade vs. book update issue)
  - Clock sync becomes simple
- Algos
  - Reduce incentive to trade off robustness for speed
- Regulators
  - Simplifies audit trail: no need to adjust for latency, relativity
  - "Level playing field" in access to public info – impossible in continuous time
- Investors
  - Easier to assess best execution.

Costs and Benefits of Frequent Batch Auctions

- Benefits
  - Enhanced liquidity
  - Eliminate socially wasteful arms race
  - Computational benefits of discrete time
- Costs
  - Investors must wait until the end of the batch interval to transact
- We should also be wary of unintended consequences
  - But remember that the continuous market has itself had numerous unintended consequences which discrete time directly addresses

Alternative Responses to the HFT Arms Race

- Numerous alternative responses: mostly address symptoms, not root cause
- "Bans" on HFT
  - Message ratios, minimum resting times
  - Misunderstand cause and effect
  - Resting times likely to exacerbate sniping
- Taxes on HFT
  - Transaction tax directionally addresses sniping but is a blunt instrument
    - tax would need to be large to effect the arms race
    - cost gets passed on to investors
  - Cancellation tax would increase cost of liquidity provision, which naturally requires cancellations as prices move
  - Tax avoidance + increased complexity
- IEX speed bump + price sliding to NBBO midpoint
  - Eliminates sniping ...
  - But only for non-displayed "pegged" orders that free-ride off of prices discovered elsewhere (see SEC comment letter)

Chicago Question

If discrete time is such a good idea, why isn't somebody already doing it?

Why Aren't Exchanges Already Doing This?

1. Relatively new idea
   - Auctions of course are an old idea, but this specific market design is new (and is importantly different from traditional call auctions, beyond just the frequency)
   - New ideas take time to be adopted

Why Aren't Exchanges Already Doing This?

2. Regulatory ambiguities
   - Reg NMS in US implicitly assumes continuous time (see my IEX comment letter)
   - SEC Chair White, in her June 2014 speech "Enhancing our Equity Market Structure":

     I am personally wary of prescriptive regulation that attempts to identify an optimal trading speed, but I am receptive to more flexible, competitive solutions that could be adopted by trading venues. These could include frequent batch auctions or other mechanisms designed to minimize speed advantages. . . . A key question is whether trading venues have sufficient opportunity and flexibility to innovate successfully with initiatives that seek to deemphasize speed as a key to trading success in order to further serve the interests of investors. If not, we must reconsider the SEC rules and market practices that stand in the way.

Why Aren't Exchanges Already Doing This?

3. Coordination Challenge
   - Need to coordinate algorithmic liquidity providers, broker-dealers, investors, etc.
   - This is a standard issue in starting a new marketplace
4. Vested Interests in the Status Quo
   - Exchanges provide arms for the arms race
     - Colocation
     - Latency-sensitive data feeds
     - Substantial proportion of exchange revenues (>60% for BATS in 2011 per S-1 filing)
   - The fact that frequent batch auctions improve market quality does not imply that they improve exchange profitability

So, What Next?

- How do we get from continuous-time –> discrete-time?
- Approach 1: private sector innovation.
  - Potential frictions:
    - Regulatory ambiguities
    - Coordination challenge
    - Vested interests in the current market structure
- Approach 2: regulatory intervention
  - Potential friction: chicken-and-egg problem
    - Regulatory authorities want a high level of proof (rightly so).
    - But, to fully prove the case, someone has to try it first.
- Three things we can hopefully all agree on
  1. Eliminate regulatory ambiguities
  2. Value of a pilot test
  3. Data availability for researchers (currently either very expensive or altogether impossible)

Summary

- We take a market design perspective to the HFT debate.
- Root problem isn't "evil HFTs", it's continuous-time trading.
- Alternative: discrete-time trading

1. Direct-feed data: continuous-time markets don't actually work in continuous time: correlations completely break down; frequent mechanical arbs; never-ending arms race
2. Theory: root cause is the current market design
3. Solution: frequent batch auctions
    - Enhances liquidity
    - Eliminates sniping
    - Stops the latency arms race
    - Simplifies the market
